# Fine-Grained Domain Relevance

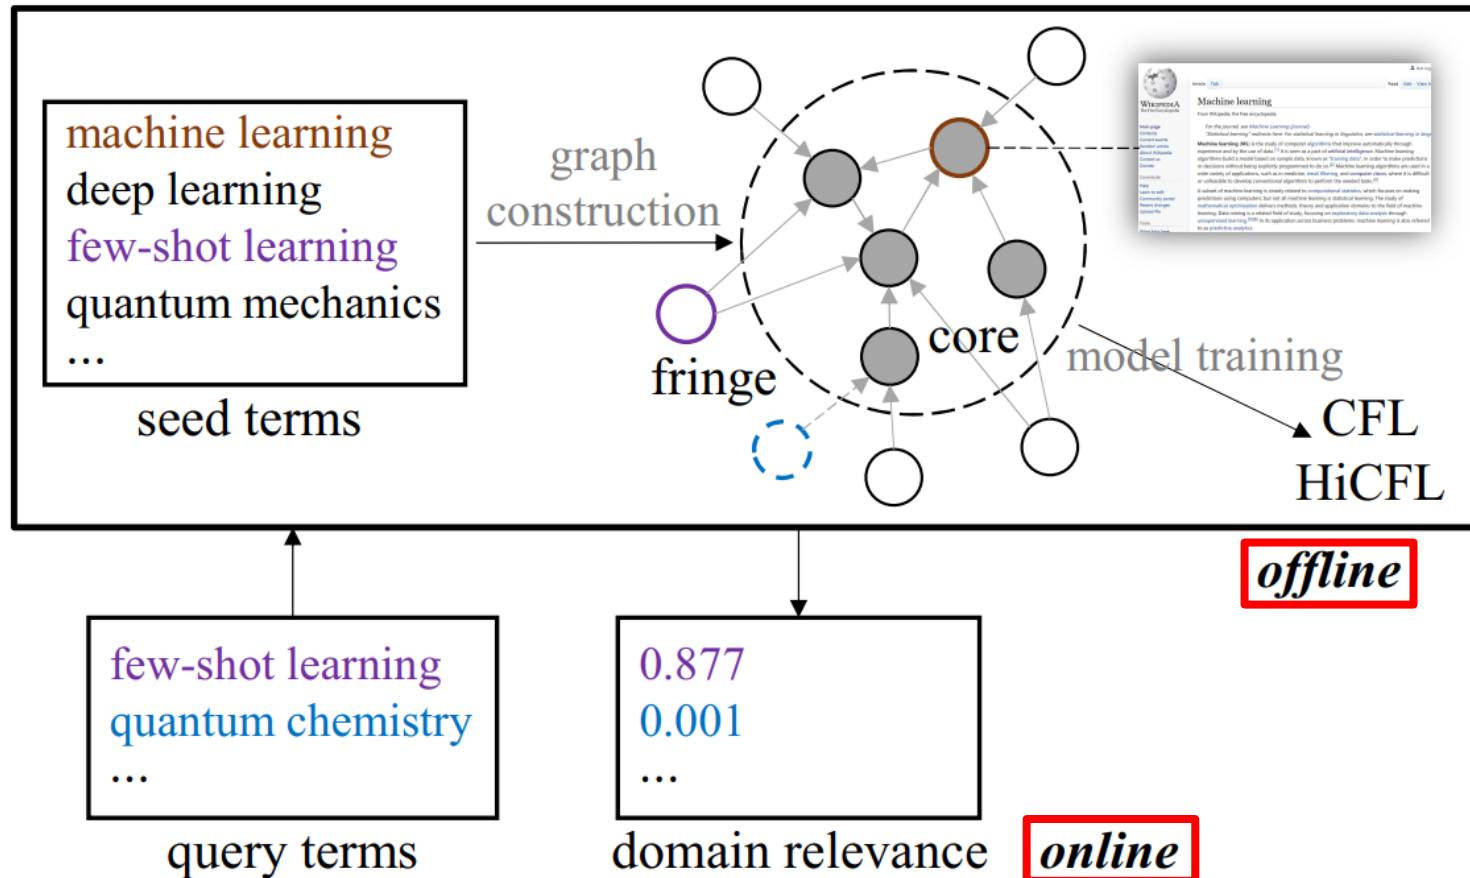

## ***Fine-grained domain relevance:***

*The degree that a term is relevant to a given domain, and the given domain can be broad or narrow*

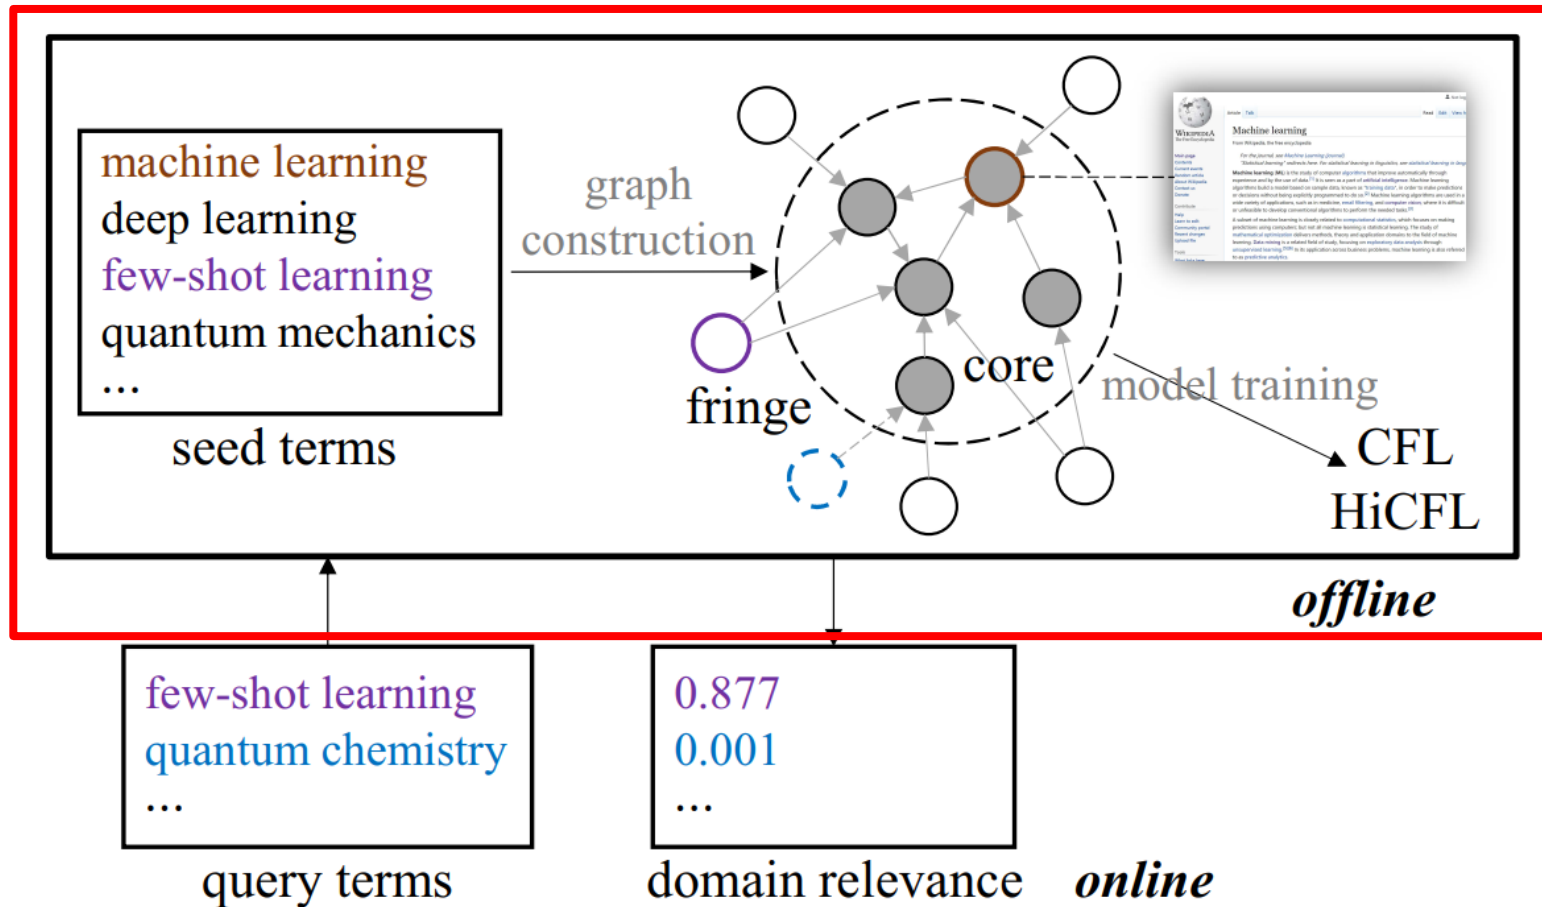

# Applications

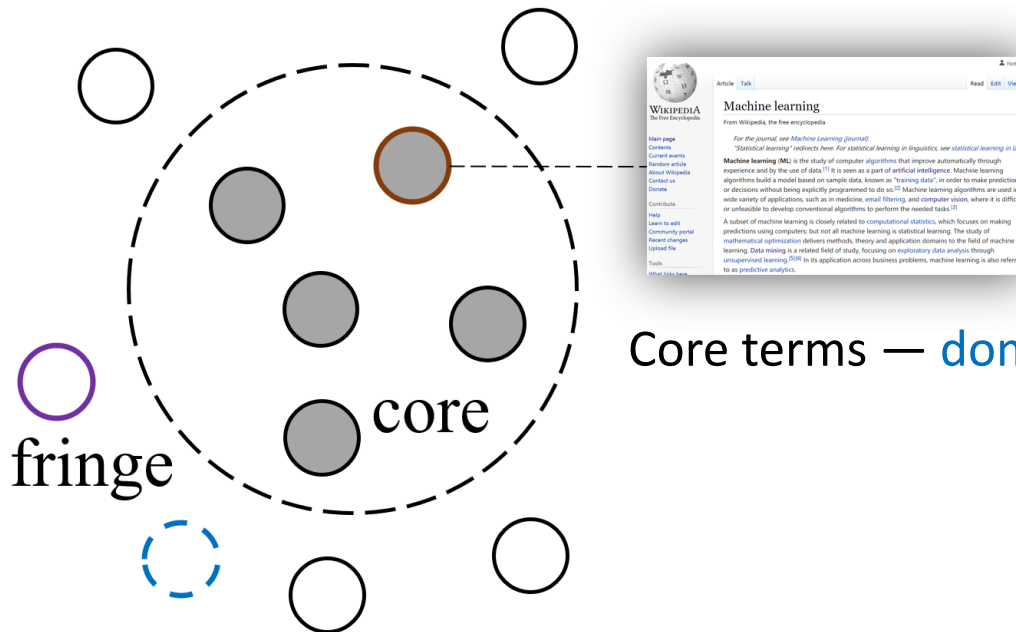

# Method: Overview

# Method: Offline

# Core-Anchored Semantic Graph

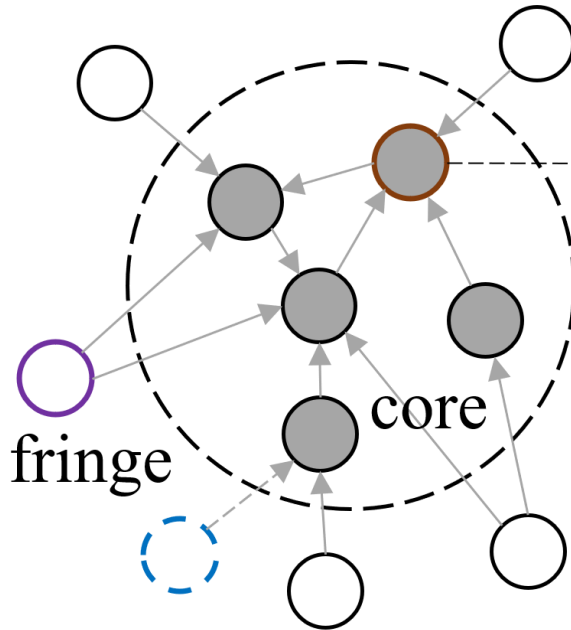

Core terms — domain relevance is easy to judge!

**Core terms:** Terms associated with rich description information (Wikipedia article pages), e.g., *Machine Learning*

**Fringe terms:** Terms without rich description information, e.g., *Few-Shot Learning* (usually the long-tail ones)

# Core-Anchored Semantic Graph

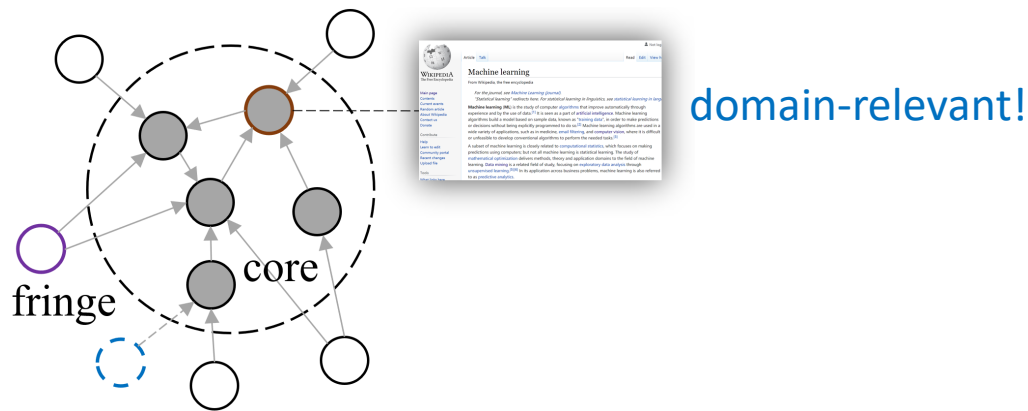

*Connect fringe terms to relevant core terms via document ranking*

***“Bridge domain relevance of terms through term relevance”***

# Core-Fringe Learning (CFL)

Assume labels of core terms (domain-relevant or not) are available:  
 $\Rightarrow$  **a) propagate features of terms via term graph**  
**b) use labels of core terms for supervision**

**Graph convolution:** 
$$h_i^{(l+1)} = \phi \left( \sum_{j \in \mathcal{N}_i \cup \{i\}} \frac{1}{c_{ij}} \mathbf{W}_c^{(l)} h_j^{(l)} + \mathbf{b}_c^{(l)} \right)$$

**Loss:** 
$$\mathcal{L} = - \sum_{i \in \mathcal{V}_{core}} (y_i \log z_i + (1 - y_i) \log(1 - z_i))$$
  
 Domain Relevance

# Hierarchical Core-Fringe Learning (HiCFL)

**Hierarchy of domains:** CS  $\rightarrow$  AI  $\rightarrow$  ML

*“An ML term should also be relevant to CS”*  $\Rightarrow$  **Hierarchical Learning**

**Global information:** 
$$\mathbf{z}_p = \sigma(\mathbf{W}_p^{(l_p)} \mathbf{a}_p^{(l_p)} + \mathbf{b}_p^{(l_p)})$$

$$\mathbf{a}_p^{(l+1)} = \phi(\mathbf{W}_p^{(l)}[\mathbf{a}_p^{(l)}; \mathbf{h}^{(l_c)}] + \mathbf{b}_p^{(l)})$$

**Local information:** 
$$\mathbf{z}_q^{(l)} = \sigma(\mathbf{W}_q^{(l)} \mathbf{a}_q^{(l)} + \mathbf{b}_q^{(l)})$$

$$\mathbf{a}_q^{(l)} = \phi(\mathbf{W}_t^{(l)} \mathbf{a}_p^{(l)} + \mathbf{b}_t^{(l)})$$

**Loss:** 
$$\mathcal{L}_h = \epsilon(\mathbf{z}_p, \mathbf{y}^{(l_p)}) + \sum_{l=1}^{l_p} \epsilon(\mathbf{z}_q^{(l)}, \mathbf{y}^{(l)})$$

**Domain relevance:** 
$$\mathbf{s} = \alpha \cdot \mathbf{z}_p + (1 - \alpha) \cdot (\mathbf{z}_q^{(1)} \circ \mathbf{z}_q^{(2)}, \dots, \mathbf{z}_q^{(l_p)})$$

## Zero-shot learning

From Wikipedia, the free encyclopedia

Subcategories

This category has the following 17 subcategories, out of 17 total.

**Zero-shot learning** (ZSL) is a machine learning paradigm where models are trained on classes that were not seen during training. These models are then used to classify new classes, often using methods generally world knowledge. For example, a model trained on images of animals to be able to recognize new images of animals to be able to recognize zebras look like striped and machine perception.

Categories: Machine learning algorithms | **Computer vision**

*Machine learning algorithms* and *Computer vision* are categories in CS  
=> **Zero-shot learning is domain-relevant!**

# Hierarchical Positive-Unlabeled Learning

For narrow domains like *Deep Learning*, a category tree might not be available in Wikipedia. **Automatic Annotation is impractical**  
 $\Rightarrow$  **Hierarchical Positive-Unlabeled (PU) Learning**

For *Deep Learning* (DL),

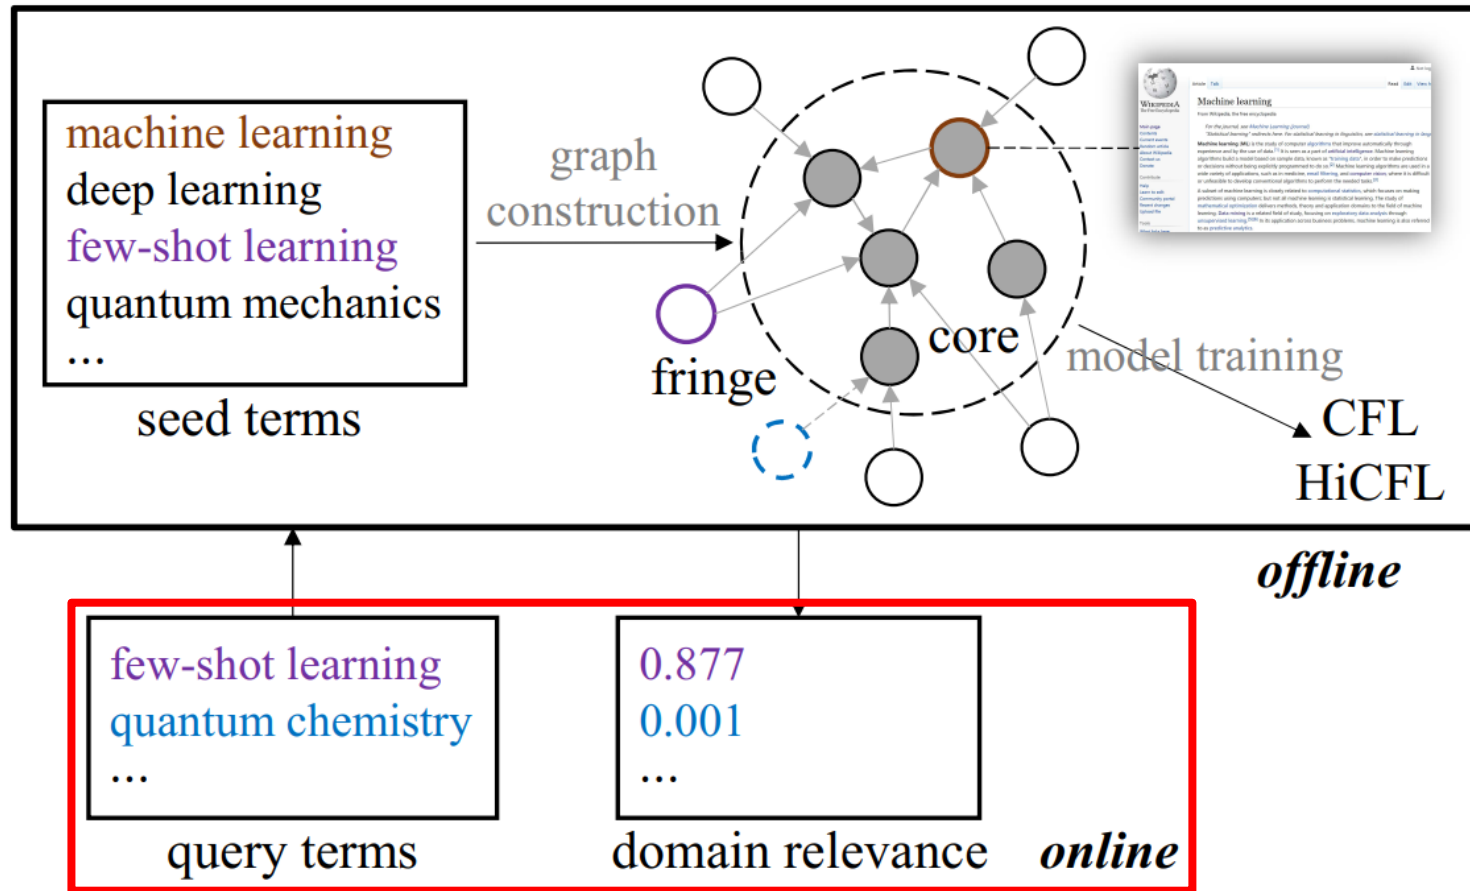

Hierarchy of domains: CS  $\rightarrow$  AI  $\rightarrow$  ML  $\rightarrow$  DL

Automatic Annotation      Positive:  $k$  DL terms provided by users  
 Negative: non-ML terms

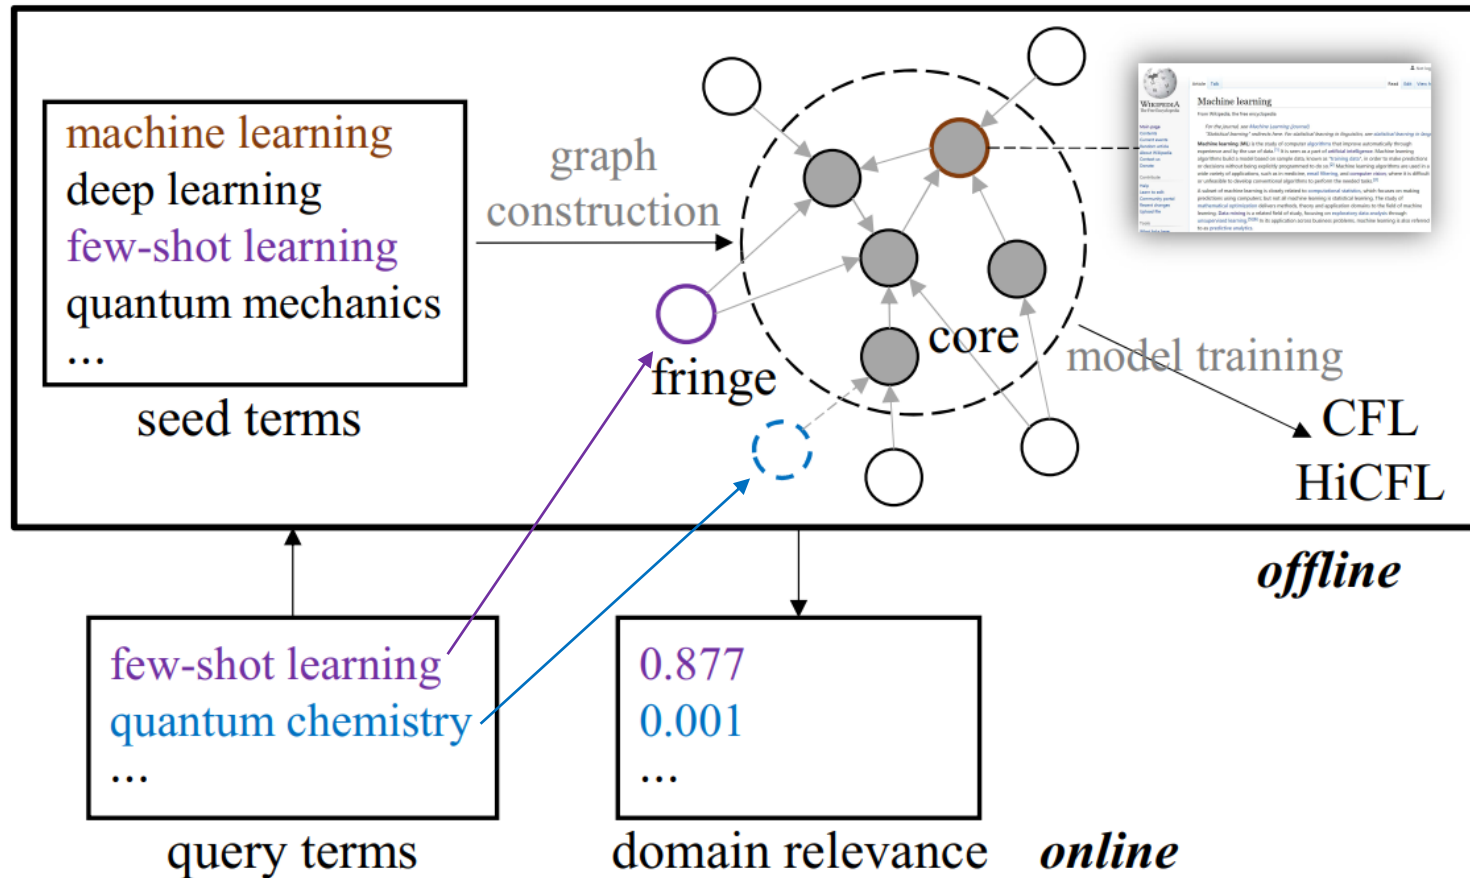

HiCFL

$$\mathcal{L}_h = \epsilon(\mathbf{z}_p, \mathbf{y}^{(l_p)}) + \sum_{l=1}^{l_p} \epsilon(\mathbf{z}_q^{(l)}, \mathbf{y}^{(l)})$$

# Method: Online

# Method: Online

# Experiments: Overview

**Comparison to Baselines:** Compare with existing methods on *Automatic Term Extraction*

**Comparison to Human Performance:** Compare with human professionals

**Case Studies:** Case studies for ML and DL

domain		#terms	core ratio
CS	ML	113,038	27.7%
Phy	QM	416,431	12.1%
Math	AA	103,984	26.4%

**Statistics of data.** 3 broad domains, 3 narrow domains

# Comparison to Human Performance

	ML-AI	ML-CS	AI-CS
Human	0.698 $\pm$ 0.087	0.846 $\pm$ 0.074	0.716 $\pm$ 0.115
HiCFL	<b>0.854</b> $\pm$ 0.017	<b>0.932</b> $\pm$ 0.007	<b>0.768</b> $\pm$ 0.023

Let humans (5 senior students majoring in CS) and machines judge which term in a query pair is more relevant to ML

*HiCFL far outperforms human performance!*

# Case Studies

The depth of the background color indicates the domain relevance. The darker the color, the higher the domain relevance (annotated by the authors); \* indicates the term is a core term, otherwise it is a fringe term.

## Deep Learning (HiCFL, PU Learning)

*Unlabeled positive terms like artificial neural network, generative adversarial network are ranked very high*

*Terms ranked 101<sup>st</sup> to 110<sup>th</sup> are all highly relevant to DL;*

*Terms ranked 1001<sup>st</sup> to 1010<sup>th</sup> are related to ML*

# Conclusion

- We propose to measure ***fine-grained domain relevance*** — the degree that a term is relevant to a given domain (broad or narrow)
- To handle long-tail terms, we design a novel **core-anchored semantic graph** to bridge domain relevance of terms
- To leverage the graph and domain hierarchy, we propose **hierarchical core-fringe learning**
- To reduce human efforts, we employ **automatic annotation** and **hierarchical positive-unlabeled learning**
- Extensive experiments demonstrate that our methods outperform strong baselines and even surpass professional human performance
